Manage headlands, vegetation buffers, drains and sediment traps to capture and or filter runoff from crop production areas.

Water quality

Vegetated filter strips and grass buffers have proved effective in the management and trapping of sediment and attached nutrients leaving paddocks. Riparian buffer strips can also help to reduce stream bank erosion, provide wildlife habitat and landscape connectivity (27S).

Experiments in the Wet Tropics:

To date no information has been found in relation to sugarcane. However, there is evidence from other horticulture industries. Trials on a banana farm in the Johnstone River catchment have shown that grass buffer/filter strips were able to reduce the sediment levels in runoff leaving the farm by more than 80%. Decreases in nitrogen, phosphorus and suspended sediment were also recorded with levels between 25% and 65% (14S & 15S).

Costs and benefits

There were no examples found of the economic impacts (either positive or negative) to a grower how applies an integrated pest and weed management plan. It is anticipated that relevant information may be provided in the near future as further research is undertaken.

Regional studies Wet Tropics

A 2004 modelling exercise conducted on a farm in the Cairns district indicated that improved drain management as part of a system of improved practices, enhanced environmental outcomes. However, it was not economically viable due to the costs of maintenance and depreciation. The improved drain system included a change from conventional drains to a spoon-shaped cane drains. The new system showed a 75% reduction in drain erosion (33S & 32S).

The adoption of a managed legume fallow, reduced tillage and the establishment of grassed headlands resulted in an overall reduction in production costs. This also resulted in improved environmental benefits (32S).

There were no examples for the other sugarcane producing regions of the Burdekin, Mackay-Whitsunday and Burnett-Mary of the economic impacts (either positive or negative) to a grower managing headlands, vegetation buffers, drains and sediment traps. It is expected that relevant information may be provided in the near future as further research is undertaken.
Sugarcane extension services

**Smartcane BMP**

This program assists growers to ensure their practices on farm are at industry standard. It was released in December 2013. It was developed by CANEGROWERS and funded by the Queensland Government.

**Fertcare**

This program is a joint initiative of the Australian Fertiliser Services Association and the Fertiliser Industry Federation of Australia. It provides training, quality assurance, certification and accreditation. The training program delivers training in managing food safety, environment and occupational health and safety risks associated with the storage, handling and use of fertilizer and soil ameliorant products.

Email: fertilizer@fifa.asn.au

**Project catalyst**

Project Catalyst is a partnership between Reef Catchments NRM, the Coca-Cola Foundation, WWF and Mackay Whitsunday sugarcane farmers. The project has also expanded into, both, the Wet Tropics and Dry Tropics NRM regions. It aims to improve water quality and reduce the impact of pollution in the Great Barrier Reef, using innovative land practices.

**Sugarcane economic tools**

**Farm Economic Analysis Tool for sugarcane**

Developed by the Department of Agriculture, Fisheries and Forestry, this excel spreadsheet is designed to assist growers in assessing the profitability in changes to their farm management practices.

Phone: 13 25 23 (DAFF)

**Supplementary resources**

**SmartCane best management practice booklet series**

Developed by BSES, Canegrowers and EPA, this series of seven booklets provides an overview of general principles of best management practice related to various aspects of a crop cycle.

Wetlands management handbook

Farm Management Systems (FMS) guidelines for managing wetlands in intensive agriculture. Developed by the Australian and Queensland governments, as part of the Queensland Wetlands Program. The guide provides information to landholders and extension officers on:

- Identifying wetlands
- Wetland management
- Artificial wetland creation

The guide was designed to complement other industry FMS programs, for holistic farm management.

Why consider improved practices?

There are expected economic benefits for farmers in transitioning towards a system of improved management practices. This is based on economic analyses that have been undertaken on farming system practices in each of the sugarcane producing regions of the Wet Tropics, Mackay-Whitsunday, Lower Burdekin and Burnett-Mary.

Economic analyses have shown that it is possible for a farming enterprise to improve profitability whilst operating with improved management practices. It is recommended that you assess your specific farming circumstances before undertaking any practice changes.

Is there any evidence that improved practices have a benefit for my farm?

Wet Tropics study one

Economic studies in the Tully region have indicated that adopting improved management practices may be economically viable. Benefits included a higher gross margin and positive net present value. This was demonstrated when the farm transitioned from C class to B class management practices over a five to 10 year period (26S & 23S).

Wet Tropics study two

In 2004, modelling of a typical farm near Cairns showed that incorporating improved practices of reduced tillage, legume fallow and reduced nitrogen application leads to an increase in income levels. Although this analysis indicated a small reduction in crop yield, financial returns were enhanced through a reduction in tillage operations, increased efficiencies and inputs over a full crop cycle. Overall, operating with these combined improved practices provides important

economic benefits to a farmer at the plot level and provides positive effects on profitability (30S & 32S).

**Mackay-Whitsunday**

Economic analysis of a 150ha demo farm in the Mackay region indicated that transitioning to a system of improved management practices may have a negative impact on profitability over the short to medium term. Results demonstrated a higher farm gross margin when adopting practice changes. However, the substantial capital costs may result in a negative return on investment in some instances. It is recommended you assess your specific farming circumstances before changing any management practices (5S).

**Burdekin**

Economic analyses of demo farms in the Burdekin region have indicated that adopting improved management practices may be economically viable. Benefits included a higher gross margin and positive net present value. This was demonstrated when a farm transitioned from C class to B class management practices over a five to 10 year period (21S & 22S & 24S & 25S).

**Burnett-Mary**

A 2006 case study of a mixed cropping farm in the Burnett-Mary (943ha cane and 160ha peanuts), showed there are benefits in adopting improved management practices. The changes included controlled traffic with GPS, reduced tillage, scheduled flood irrigation and fallow legume cropping. The peanut crop was slashed, left on the ground and worked into the soil prior to planting the sugarcane. The study indicated a significant increase in gross margin over a projected 10 year timeframe with increases in labour efficiency and reduced tractor hours. Retaining peanut residue on the surface provided approximately 60 kg/ha of nitrogen. The tillage requirements for seed bed preparation were significantly reduced (11S).
